

Introduction

The objective of the project is to analyse the prison systems of different countries and compare them to each other based on what? Add that here.

Implementation techniques

Data was collected from official datasets and pdf files. We then cleaned and converted the data to a machine readable format. The data was analysed using scikit-learn and Python and visualised on our website using Vite/React/Typescript.

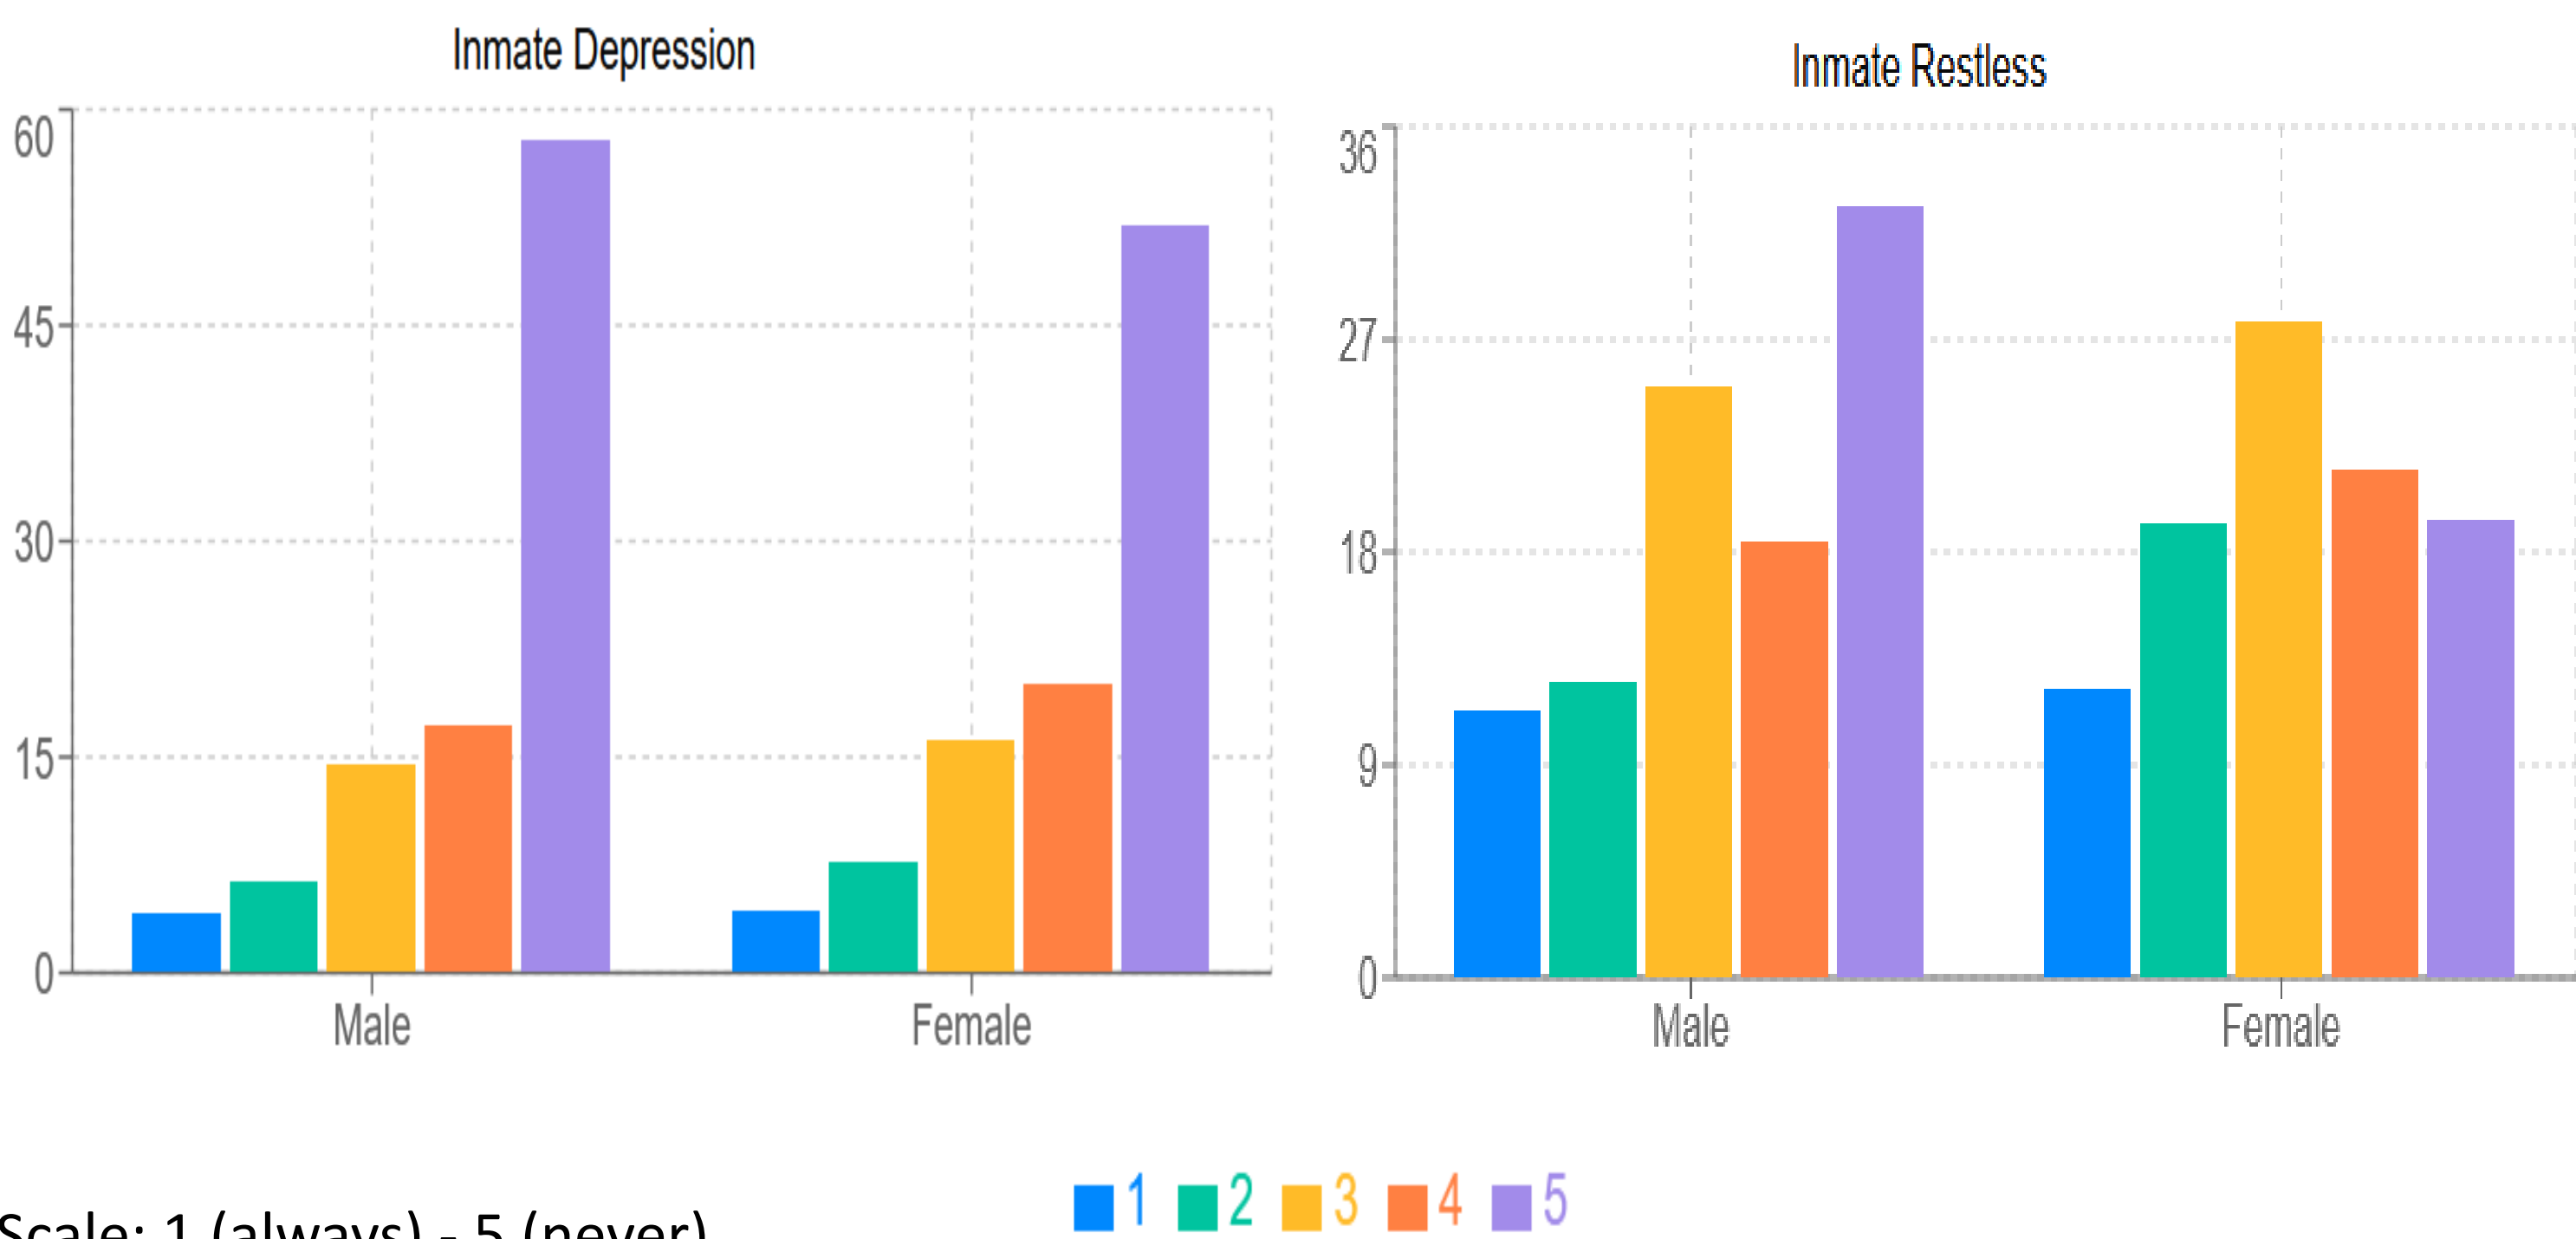

Differences in recidivism

Recidivism is the tendency of a convicted criminal to reoffend.

We analysed the likelihood of reoffending based on inmate's sex and age. As they age, men tend not to commit new felony offenses as much as women. The rates for parole violations are similar.

Mental health differences between demographics

Scale: 1 (always) - 5 (never)  
Men/Women on depression and restlessness in relative numbers

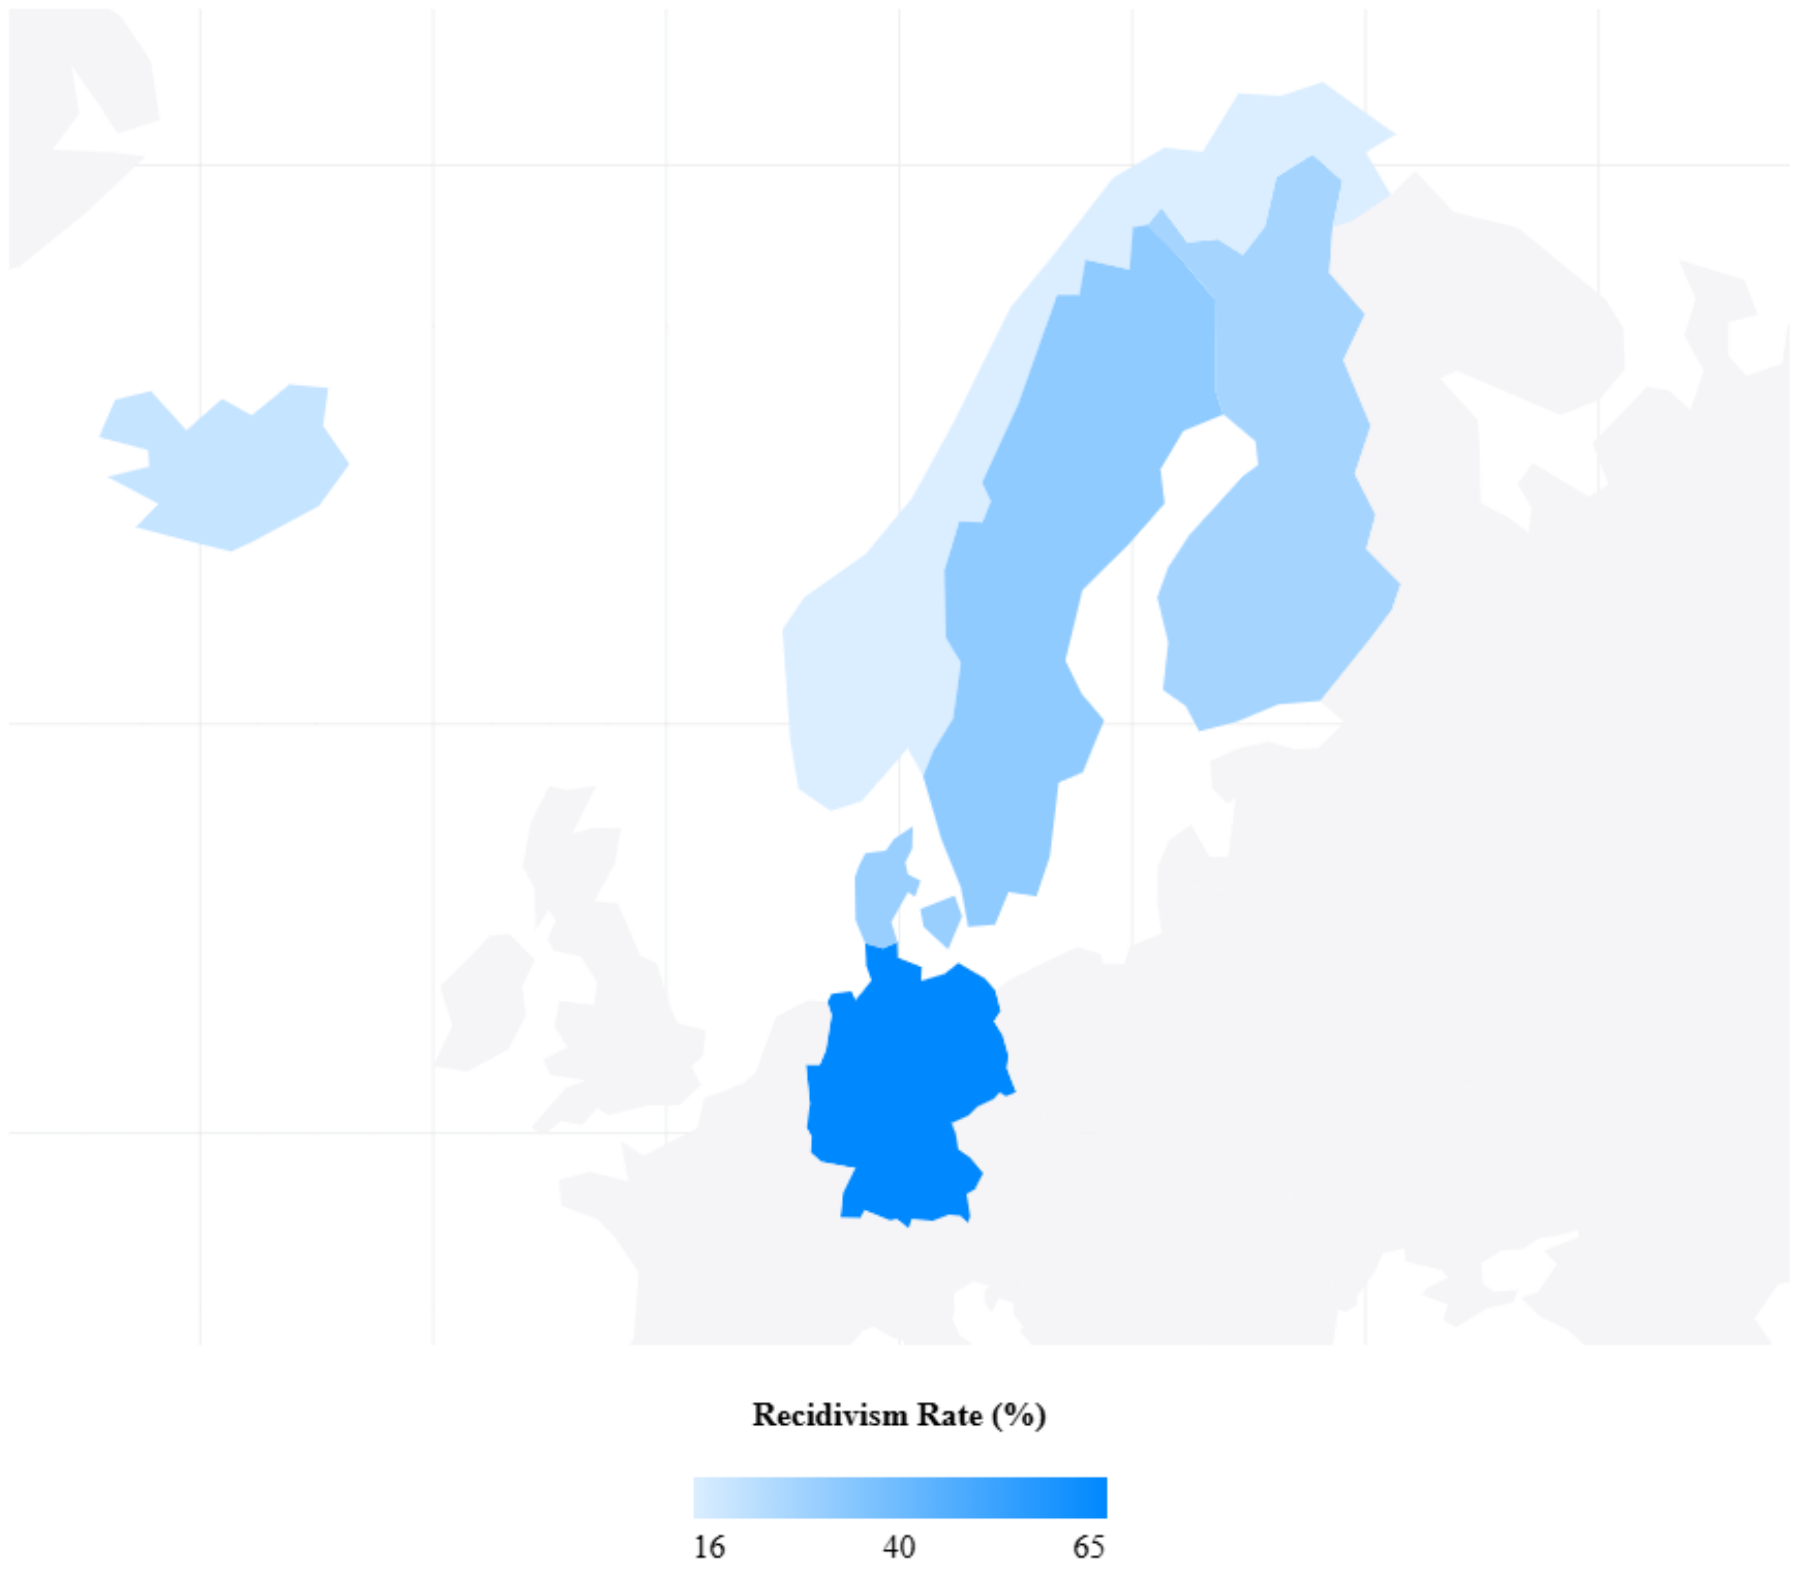

We analysed inmate mental wellbeing based on characteristics such as sex, gender, sexual orientation, and ethnicity. Although variations were observed across these factors, an inmate's sex emerged as the most significant predictor of mental wellbeing.

Recidivism rate across countries

This map visualizes the recidivism rates across Northern Europe and highlights regional differences in rehabilitation effectiveness.

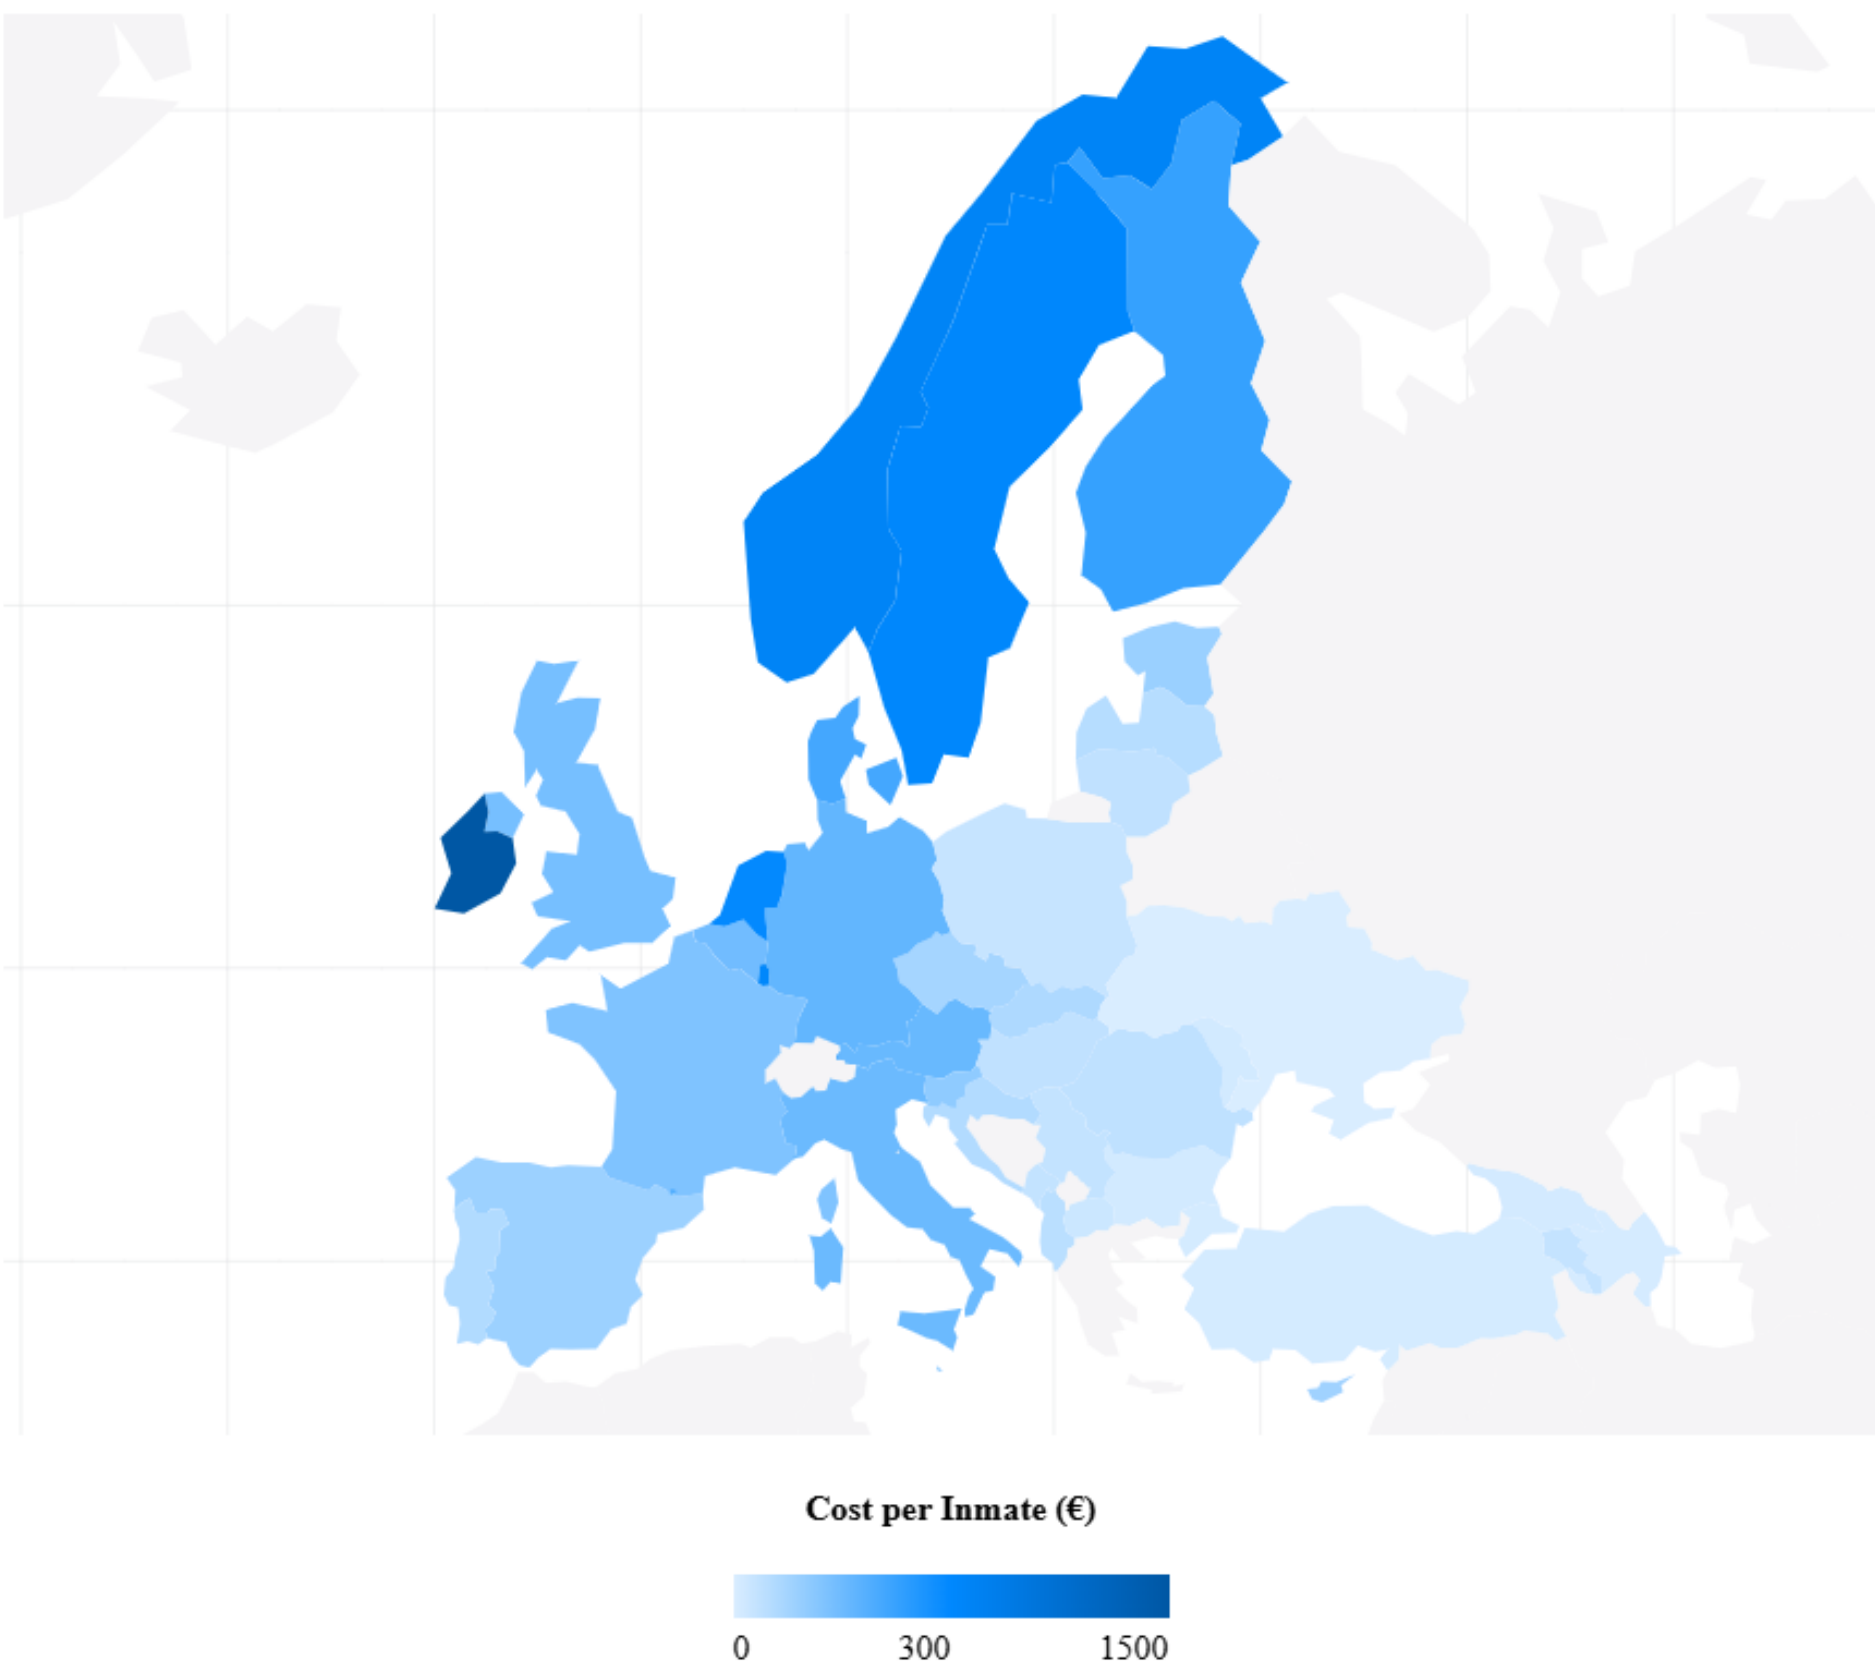

Offense distribution across countries

We found that the Distribution of Offenses varies a lot between countries, with drug offenses being the most common in total.

Costs per inmate across countries

This heat map illustrates the cost per inmate across Europe, highlighting the disparities in investments in prison systems across the continent.

We found clear trends, with Scandinavian countries and Irland spending the most on average and eastern European countries spending less.

Challenges faced

- Accessing sensitive governmental data
- Tweaking of predictive models
- Turning data from pdf files into machine readable formats
